

T1-2, Virtual Assessment of Need Sympthetic Perception of Response Capacity

The bipolar coalescence of *Form(5) ↔ Routine(4) ↔ Emotional Knowledge (3)* reflects the balance between R_1 and R_2 as a virtual conceptual image. This represents a coherent sympathetic urge to express felt need in behavior. The *Host(1)* person coalesced with *Conscious Knowledge(2)* creates the bipolar R_3 that generates the bipolar coalescence of limbic *Emotion(3)* with *Behavioral Form(5)* as a virtual *Routine(4)*. This occurs because *Host(1)* and *Consciousness(2)* perceive a common inside and outside that is also common to *Emotional Knowledge(2)* and *Behavioral Form(5)*. The virtual image results from the subjective to objective disparity across the *Routine(4)* interface that is felt as a specific urge to respond to circumstance. Note that *Behavioral Form(5)* means behavior of physical matter including chemical resources within *Routines(4)* of the body. The *Host(1)* coalesced with *Consciousness(2)* in the expressive mode *Emotionally Knows(3) Routines(4)* of *Behavioral Form(5)* as a virtual vision of action possible. *Consciousness(2)* in the other direction knows the physical *Form(4)* of available resources within *Routines(4)* as a virtual vision relating to *Known Emotions(3)*. In the regenerative mode (1) and (2) change places so that the *Host(1)* *Knows(2)* that *Resources(5)* implicit in *Routines(4)* are limited as they relate to *Known Emotions(3)*. The person is thus able to assess their resource capacity to respond to perceived need in the social market place according to the R_1 to R_2 balance implicit in the R_3 virtual concept that is emotionally felt and known. The Sympathetic nervous system is dependent on the parasympathetic system to restrain potential action sequences however which is the function of Term T1-3.
